Table 1 | Related capabilities and the guarantee being evaluated

Research line	Main object addressed	Relation to the present method
Active feature acquisition [12–16]	Predictive utility and observation cost under subset observations	May supply a feature schedule; does not substitute for checking the stated relative-loss certificate
Risk-controlled early exit [5]	Calibrated distributional risk or a final-model performance gap	Establishes the relative Brier target; the quantifier here is individual input and every label
Certified lazy boosted-tree inference [6]	Preservation of the complete winning class	Supplies a distinct output criterion, tested by score separation
Adversarial uncertainty certification [7]	Worst calibration quantities over a perturbation set	Related certification tools with a different domain and loss object
Present construction	Worst relative multiclass half-Brier loss over complete outputs consistent with observed blocks	Constructs and certifies a probability vector, while charging its full processing cost

The present objective is pointwise relative multiclass half-Brier fidelity to the complete predictor.
